# **Bash Scripting**

#### **Bash Scripts**

Reusuable sets of bash terminal commands can be created using bash scripts. Bash scripts can run any command that can be run in a terminal.

#### **Bash Shebang**

Bash script files start with #!/bin/bash . This special line tells the computer to use bash as the intepreter.

#### Bash script variables

Variables in a bash script can be set using the = sign, and accessed using \$ .

#### Bash script comparison operators

(Equal) and != (Not equal) operators.

```
In bash scripting, strings are compared using the ==
```

```
bash script read keyword
```

The read command can be used to prompt the user for input. It will continue to read user input until the Enter key is pressed.

Some prompt text can also be specified using -p with the read command.

```
greeting="Hello"
echo $greeting
```

```
#!bin/bash
word1="Hello"
word2="Hello"
word3="hello"
if [ $word1 == $word2 ]
then
  echo "Strings are equal"
fi
if [ $word1 != $word3 ]
then
  echo "Strings are not equal"
fi
```

```
#!bin/bash
echo "Press Enter to continue"
read
read -p "Enter your name: " name
```

#### **Bash Script Arguments**

Arguments can be added to a bash script after the the script's name. Once provided they can be accessed by using \$(position in the argument list). For example, the first argument can be accessed with \$1, the second with \$2, the third with \$3, etc.

## code cademy

```
#!/bin/bash
# For a script invoked by saycolors red
green blue
# echoes red
echo $1

# echoes green
echo $2

# echoes blue
echo $3
```

#### **Bash Aliases**

Aliases can be created using the keyword alias. They are used to create shorter commands for calling bash scripts. They can also be used to call bash scripts with certain arguments.

```
# For example, to create an alias that
invokes the saycolor
# script with the argument "green", the
following syntax is used:
alias saygreen='./saycolors.sh "green"'
```
